CATALOG No. 003-1EU

# THK Precision Ballscrews

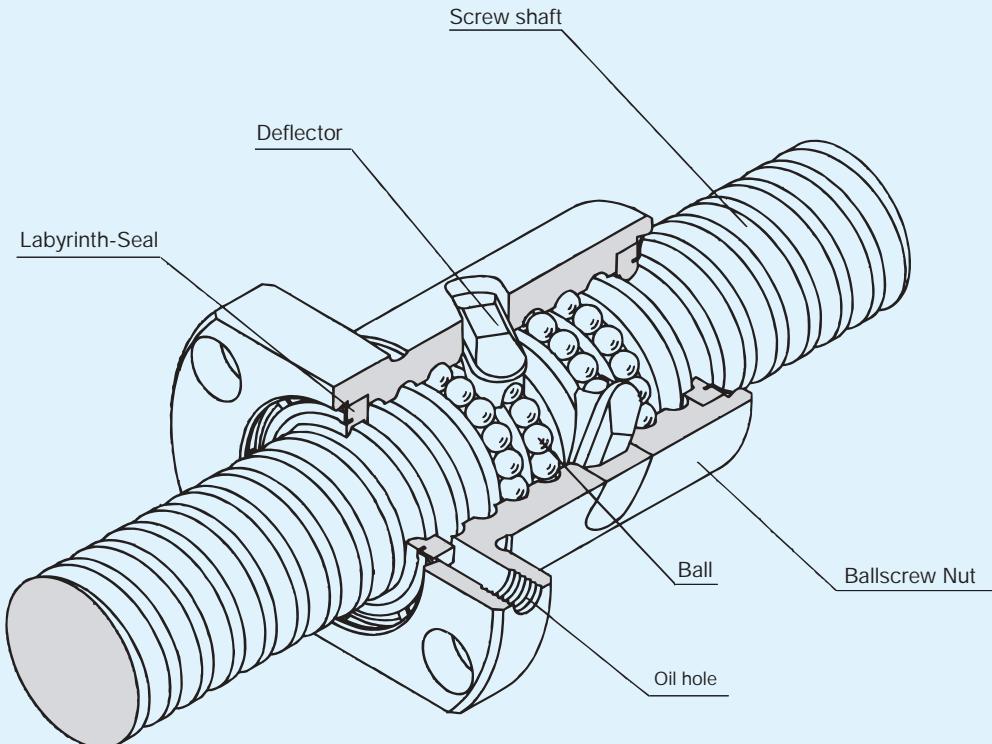

Fig. 1 Construction of a simple nut ballscrew

## • Availability

THK precision ballscrews can be delivered with the following specifications at short notice:

- according to DIN 69051, part 5 (ISO 3408-5)
- with THK standard dimensions
- with large lead

## • Precision Rolled Ballscrews

Ground precision ballscrews are best suited for applications, where high axial rigidity is required. Precision rolled ballscrews are a cost-effective alternative to ground ground ballscrews. These products match the accuracy grades of the standard DIN 69051, part 3, as well as ISO 3408-3.

Standard		JIS (Jap. industrial standard)		DIN/ISO		
Accuracy grade		C3	C5	Cp3	Cp5	Ct5
Manufacturing method		Ground		Precision rolled		
Preload	Double nut	0.05 Ca	0.05 Ca	0.05 Ca	0.05 Ca	—
	Pitch shifted	0.05 Ca	0.05 Ca	0.02 Ca	0.02 Ca	—
	Ball selection	0.02 Ca	0.02 Ca	Without clearance	Without clearance	Without clearance

## • Support Units and Screw Shafts with Finished Ends Available

THK precision ballscrews can be delivered with support units and the appropriate shaft ends.

## Product Overview

### Precision Ballscrews According to DIN 69051 (1989)

#### EPA/EBA (Form A)

Single nut preloaded/without clearance

Page 20/26

Available screw shaft diameter × lead:  
16×05 ~ 63×20

#### EPB/EBB (Form B)

Single nut preloaded/without clearance

Page 22/28

Available screw shaft diameter × lead:  
16×05 ~ 63×20

#### EPC/EBC (Form C)

Single nut preloaded/without clearance

Page 24/30

Available screw shaft diameter × lead:  
16×05 ~ 63×20

### THK Ballscrews with Standard Dimensions

#### BIF

Single nut preloaded

Page 32

Available screw shaft diameter × lead:  
16×05 ~ 63×20

#### BNF

Double nut preloaded

Page 34

Available screw shaft diameter × lead:  
16×05 ~ 63×20

#### BNF

Single nut

Page 36

Available screw shaft diameter × lead:  
16×05 ~ 63×20

### Large Lead

#### BLK

Single nut without clearance

Page 38

Available screw shaft diameter × lead:  
16×16 ~ 40×40

### Support Units

#### BK/BF - EK/EF

Page 40

# Screw Shaft Selection

## Available Diameter/Lead Combinations

The tables below indicate the standard combinations of the screw shafts and leads. If a diameter and lead combination other than those specified in the tables is required, please contact **THK**.

- Standard
- Δ Semi-Standard

## Permissible Rotational Speed

### Dangerous screw shaft speed

At high rotational speeds, the ballscrew causes resonance due to the characteristic frequency of the screw shaft, which may make operation impossible. The shaft speed should therefore be set at a level below the resonant point (critical speed).

Figure 1 indicates the relationship between screw-shaft diameter and critical speed.

Permissible rotational speed based on the critical speed can be calculated using equation (8), wherein 0.8 is used as a safety factor.

$$N_1 = \frac{60 \cdot \lambda_1^2}{2\pi \cdot \ell_b^2} \times \sqrt{\frac{E \cdot 10^3 \cdot I}{\gamma \cdot A}} \times 0.8 = \lambda_2 \cdot \frac{d_1}{\ell_b^2} \cdot 10^7$$

where

$\lambda_1$  : permissible rotational speed determined based on the critical speed ( $\text{min}^{-1}$ )

$\ell_b$  : distance between mounting positions (mm)

E : Young's modulus ( $2.06 \times 10^5 \text{ N/mm}^2$ )

I : minimum geometrical moment of inertia of the screw-shaft cross section ( $\text{mm}^4$ )

$$I = \frac{\pi}{64} \cdot d_1^4 \quad d_1: \text{Screw-shaft thread min diameter (mm)}$$

$\gamma$  : density (specific gravity) ( $7.85 \times 10^{-6} \text{ kg/mm}^3$ )

A : screw-shaft cross-sectional area ( $\text{mm}^2$ )

$$A = \frac{\pi}{4} \cdot d_1^2$$

$\lambda_1$  and  $\lambda_2$  = coefficient depending on the mounting method

Fixed/free:  $\lambda_1 = 1.875 \quad \lambda_2 = 3.4$

Supported/supported:  $\lambda_1 = 3.142 \quad \lambda_2 = 9.7$

Fixed/supported:  $\lambda_1 = 3.927 \quad \lambda_2 = 15.1$

Fixed/fixed:  $\lambda_1 = 4.730 \quad \lambda_2 = 21.9$

## DN Value

### DN value

The permissible rotational speed of the ballscrew should be determined based on the critical speed and DN value.

The permissible rotational speed determined based on the DN value can be calculated using equations (1) through (3).

- Precision-Ground Ballscrew

$$N_2 = \frac{100\,000}{D} \quad \dots \dots \dots \quad (1)$$

(For BNF, BNFN and BIF 70.000)

where

$N_2$  : permissible rotational speed determined based on the DN value ( $\text{min}^{-1}$ )

D : ball center-to-center diameter (presented in the dimension table) (mm)

- Rolled Ballscrew (excluding the large-lead type)

$$N_2 = \frac{50\,000}{D} \quad \dots \dots \dots \quad (2)$$

- Large-Lead Rolled Ballscrew (BLK)

$$N_2 = \frac{70\,000}{D} \quad \dots \dots \dots \quad (3)$$

$N_1$  or  $N_2$ , whichever is lower, is taken as the permissible rotational speed.

For operating rotational speeds greater than  $N_2$ , high-speed ballscrew models are available. If you require these models, please contact us.

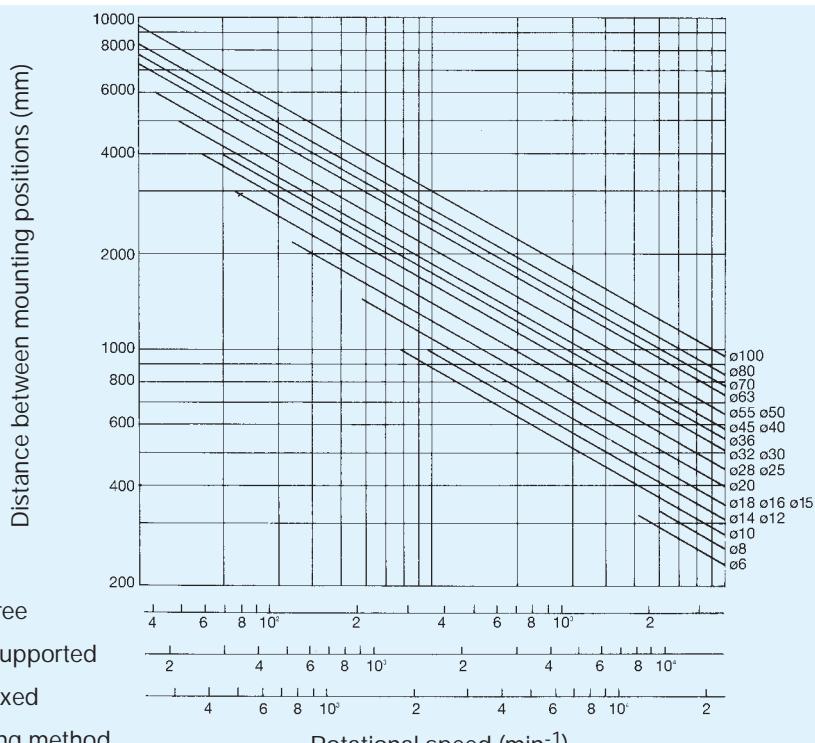

Fig. 1 Permissible-Rotational-Speed Diagram

## Permissible Axial Load

### Screw-shaft buckling load

The ballscrew to be used should not buckle under the maximum compressive load applied in its axial direction. Figure 2 shows the relationship between the screw-shaft diameter and the buckling load.

The buckling load can be calculated using equation (4), wherein 0.5 is used as a safety factor.

$$P_1 = \frac{n_1 \cdot \pi^2 \cdot E \cdot I}{\ell_a^2} \cdot 0.5 = n_2 \cdot \frac{d_1^4}{\ell_a^2} \cdot 10^4 \dots \dots \dots \quad (4)$$

where

$P_1$ : buckling load (N)

$\ell_a$ : distance between mounting positions (mm)

E : Young's modulus ( $2.06 \times 10^5$  N/mm<sup>2</sup>)

I : minimum geometrical moment of inertia of the screw-shaft cross section (mm<sup>4</sup>)

$$I = \frac{\pi}{64} \cdot d_1^4$$

$d_1$ : Screw-shaft thread min diameter (mm)

$n_1$  and  $n_2$ : coefficient depending on the mounting method

Fixed/free:  $n_1 = 0.25$      $n_2 = 1.3$

Fixed/supported:  $n_1 = 2.0$      $n_2 = 10.0$

Fixed/fixed:  $n_1 = 4.0$      $n_2 = 20.0$

### Permissible tensile-compressive load of the screw shaft

Where an axial load is exerted on the ballscrew, the screw shaft to be used should be determined in consideration of buckling load and the permissible tensile-compressive load that can exert yielding stress on the shaft.

The permissible tensile-compressive load can be calculated using equation (5).

$$P_2 = \delta \cdot \frac{\pi}{4} \cdot d_1^2 = 116 \cdot d_1^2 \dots \dots \dots \quad (5)$$

$P_2$ : permissible tensile-compressive load (N)

$\delta$ : permissible tensile-compressive stress (147 N/mm<sup>2</sup>)

$d_1$ : screw-shaft thread minor diameter (mm)

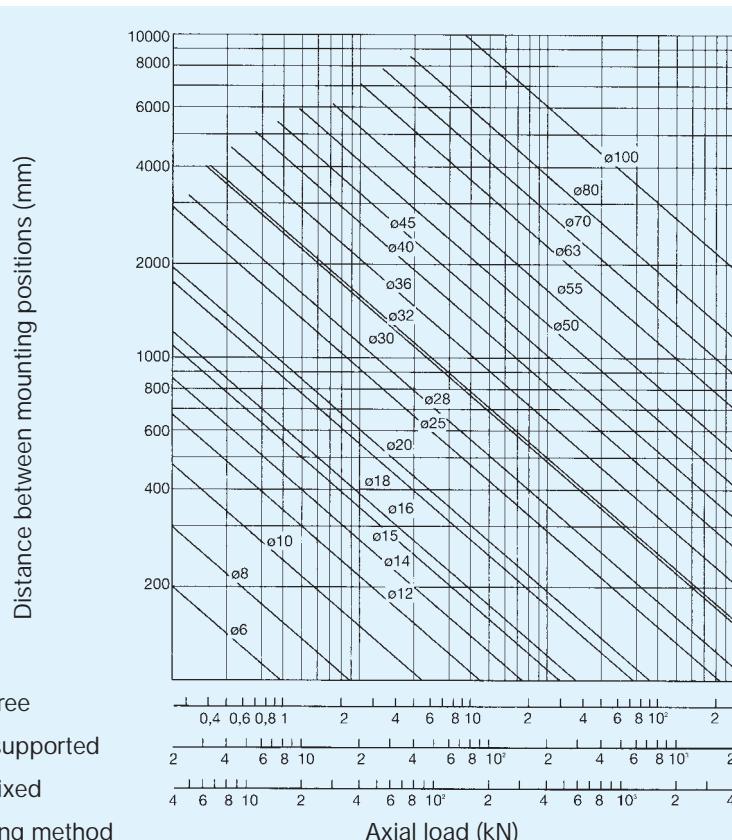

Fig. 2 Permissible-Axial-Load Diagram

## Static Safety Factor

If the ballscrew, whether at rest or in motion, receives an excessive load or significant impact, localized permanent deformation develops between the raceway and balls.

Over a certain level, the permanent deformation hinders the smooth movement of the ballscrew. Normally, the basic static load rating ( $C_{0a}$ ) is taken as the permissible axial load.

### Basic static load rating ( $C_{0a}$ )

The basic static load rating is the static load with a non-varying direction and magnitude that makes the sum of the permanent deformation of the rolling elements and raceway 0.0001 times the rolling-element diameter. With the ballscrew, the basic static load rating is defined in relation to the axial load.

Various values for the ballscrew are presented in the corresponding dimension tables in this catalog.

### Static safety factor

The basic static load rating ( $C_{0a}$ ) is normally equal to the permissible axial load of the ballscrew. Depending on the operating conditions, use of a static safety factor such as that specified below should be considered. Please be aware that the ballscrew may receive an unpredictable external force due to vibration and impact while it is at rest or in motion, or due to inertia resulting from starting and stopping.

$$F_{a \max} = \frac{C_{0a}}{f_s}$$

$F_{a \max}$  : Permissible axial load (kN)  
 $C_{0a}$  : Basic static load rating (kN)  
 $f_s$  : Static safety factor (see Table 7)

Table 7 Static Safety Factor ( $f_s$ )

Host machine	Load conditions	$f_s$ lower limit
General industrial machine	When not subjected to vibration or impact	1.0 ~ 1.3
	When subjected to vibration and impact	2.0 ~ 3.0
Machine tool	When not subjected to vibration or impact	1.0 ~ 1.5
	When subjected to vibration and impact	2.5 ~ 7.0

## Considering Service Life

### Service life of ballscrew units

The ballscrew in motion under an external load receives repeated stress on its raceways and balls. When the stress reaches a certain point, the raceways fatigue and eventually break, and their surfaces peel. Such peeling is called flaking.

The service life of a ballscrew unit is the total number of revolutions that the unit achieves before the first flaking occurs as a result of the rolling fatigue of the raceways or balls.

The service life of ballscrew units varies greatly from unit to unit, even if they are manufactured to the same specifications and remain in service under the same operating conditions. Therefore, guidelines for determining the service life of a ballscrew unit are given based on the nominal life, which is defined below.

The nominal life is the total number of revolutions that 90% of identical ballscrew units in a group, when operated independently of one another under the same conditions, can achieve without developing flaking.

### Basic dynamic load rating $C_a$

The basic dynamic load rating ( $C_a$ ) of the ballscrew is used to calculate its service life when it is operated under a load.

The basic dynamic load rating ( $C_a$ ) is the load with a nonvarying direction and magnitude that makes the nominal life  $L$  of identical ballscrew units in a group, when operated independently of one another,  $10^6$  (revolutions). (Basic dynamic load rating  $C_a$  is presented in the corresponding dimension tables.)

The dynamic load  $C_a$  is based on the calculation method according to ISO 3408-5 respectively DIN 69051 (1989). This calculation method is defined by the European and Japanese ballscrew manufacturers as a universally valid standard.

### Service-life calculation

The nominal life of the ballscrew can be calculated by an equation (6) using the values for the basic dynamic load rating ( $C_a$ ) and applied axial load.

#### (1) Nominal life (total number of revolutions)

$$L = \left( \frac{C_a}{f_w \cdot F_a} \right)^3 \cdot 10^6 \dots \dots \dots \dots \dots \dots \quad (6)$$

where

$L$ : nominal life (total number of revolutions)	(rev) (min <sup>-1</sup> )
$C_a$ : basic dynamic load rating	(N)
$F_a$ : applied axial load	(N)
$f_w$ : load factor	(see table 8)

Table 8 Load Factor ( $f_w$ )

Vibration and impact	Velocity (V)	$f_w$
Very light	Very low: $V \leq 0.25 \text{ m/s}$	1.0 ~ 1.2
Light	Low: $0.25 < V \leq 1.0 \text{ m/s}$	1.2 ~ 1.5
Medium	Intermediate: $1.0 < V \leq 2.0 \text{ m/s}$	1.5 ~ 2.0
Heavy	High: $V > 2.0 \text{ m/s}$	2.0 ~ 3.5

## (2) Service life in hours

If the number of revolutions per minute is known, the service life in hours can be calculated by an equation (7) using the value for the nominal life (L).

$$L_h = \frac{L}{60 \cdot n} = \frac{L \cdot \ell}{2 \cdot 60 \cdot S \cdot \ell_s} \quad \dots \dots \dots (7)$$

where

- |  |                      |
|--|----------------------|
| $L_h$ : service life in hours                  | (h)                  |
| n : number of revolutions per minute           | (min <sup>-1</sup> ) |
| S : number of reciprocal operations per minute | (min <sup>-1</sup> ) |
| $\ell$ : ballscrew lead                        | (mm)                 |
| $\ell_s$ : stroke length                       | (mm)                 |

## (3) Service life in running distance

This can be calculated by an equation (8) using the values for the nominal life (L) and the ballscrew lead.

$$L_s = \frac{L \cdot \ell}{10^6} \quad \dots \dots \dots (8)$$

where

- |  |      |
|--|------|
| $L_s$ : service life in running distance | (km) |
| $\ell$ : ballscrew lead                  | (mm) |

## (4) Applied load and service life in consideration of the preload

For a ballscrew used with a preload applied to the nut, the service life should be calculated in consideration of the preload, which is the internal load on the nut. If you have questions about the preload, please contact us, and be sure to specify the relevant model number.

## (5) Mean axial load

When the axial loads applied to the ballscrew fluctuate, the service life should be calculated based on the mean axial load of the varying axial loads.

The mean axial load ( $F_m$ ) is the load that makes the service life of the ballscrew equivalent to that under varying loads exerted during operation.

Where loads vary incrementally, the mean axial load can be obtained using the following equation:

$$F_m = \sqrt[3]{\frac{1}{L} (F_{a1}^3 \ell_1 + F_{a2}^3 \ell_2 + \dots + F_{an}^3 \ell_n)} \quad \dots \dots \dots (9)$$

- |  |      |
|--|------|
| $F_m$ : mean axial load  | (N)  |
| $F_{an}$ : varying load  | (N)  |
| $\ell_n$ : running distance achieved under load ( $F_n$ ) (mm) |      |
| L : total running distance                                     | (mm) |

To determine the service life in the number of revolutions or hours instead of distance, obtain the distance using the equation shown below, and calculate the mean axial load.

$$\begin{aligned} \ell &= \ell_1 + \ell_2 + \dots + \ell_n \\ \ell_1 &= N_1 \cdot t_1 \\ \ell_2 &= N_2 \cdot t_2 \\ \ell_n &= N_n \cdot t_n \end{aligned}$$

where

- |                           |  |
|---------------------------|--|
| N : number of revolutions |  |
| t : time                  |  |

# Ballscrew Accuracy Grades

## Travel Variation and Travel Deviation

The accuracy grades of the precision rolled ballscrews are related to standards ISO 3408 and DIN 69051. The accuracy grades of the ground ballscrews are controlled in accordance of the Japanese standard JIS B 1191 and JIS B 1192.

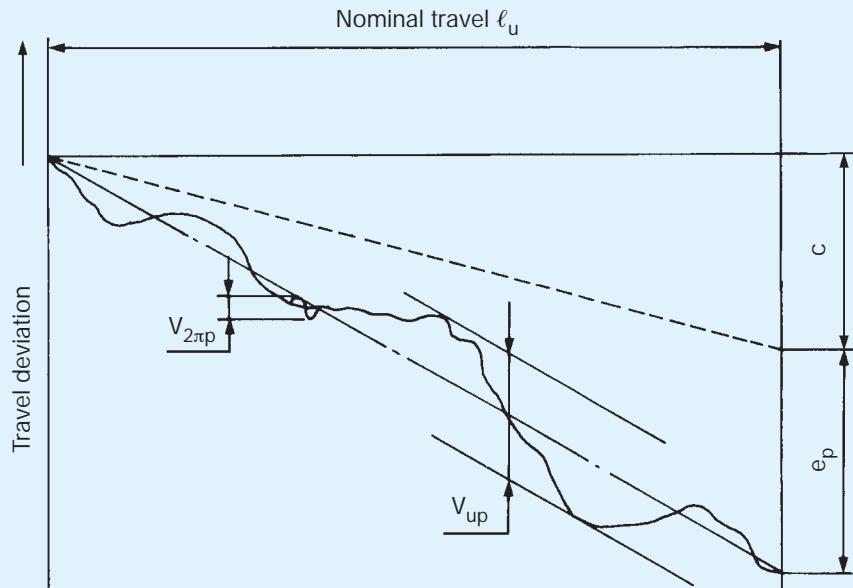

Figure 3 Permissible travel deviation and travel variation in relation to the nominal travel

### Definitions according to ISO 3408:

- $e_p$ : Tolerance on specified travel. The difference between the maximum and minimum values of the permissible actual mean travel.
- $V_{up}$ : Permissible travel variation in relation to the nominal travel  $\ell_u$ .
- $V_{2\pi p}$ : Permissible travel variation in relation to one rotation  $2\pi$  rad.
- $V_{300p}$ : Permissible travel deviation over 300 mm travel.
- $c$ : Travel compensation. The difference between the specified travel and nominal travel within the useful travel (Standard:  $c = 0$ ).

Table 1 Tolerance on specified travel  $\pm e_p$  and permissible travel variation  $V_{up}$  in relation to the nominal travel  $\ell_u$  for positioning ballscrews.

## Mounting Surface Accuracy C3 and C5

The mounting surface for the accuracy grades C3 and C5 of the ground precision ballscrews is specified in the Japanese standard JIS.

**Only valid for the types BIF, BNFN, BNF, EB and EP**

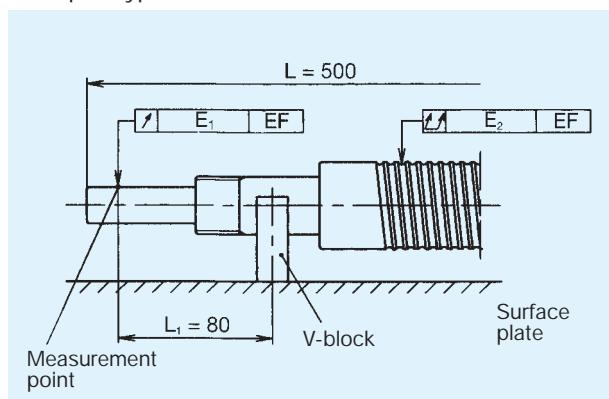

Notes: The overall radial runout of the screw shafts axis is defined in JIS B 1191 and 1192. For the radial run-out see table 8.

Table 4 Radial runout of the journal diameter in respect to EF

Shaft diameter $d_0$ (mm)		Journal diameter (max.)		Unit: $\mu\text{m}$
THK Accuracy grade		C3	C5	
Over	Up to (incl.)			
12	20	9	12	
20	32	10	13	
32	50	12	15	

Notes: For more detailed information see JIS B 1191 and JIS B 1192.

Example: Type BIF2005-RRG0 + 500LC5

$$E_1 = e + \Delta e$$

e: Standard value in table 4 (0.012)

$\Delta e$ : Corrected value

$$\Delta e = \frac{L_1}{L} \cdot E_2$$

$E_2$ : Overall radial runout in respect to EF according JIS.

$$= \frac{80}{500} \cdot 0.060 = 0.010$$

$$E_1 = 0.012 + 0.010 = 0.022$$

Notes: The overall runout of the thread root as seen in table 4 depends on the overall runout of the screw shaft.

Therefore, like in the example, the proportion between the screw shaft length L and the measurement point must be set.

$d_0$  = Screw shaft outer diameter [mm]

$\ell_5$  = Reference length [mm]

Notes: For more detailed information and test instructions see  
DIN 69051, part 3.

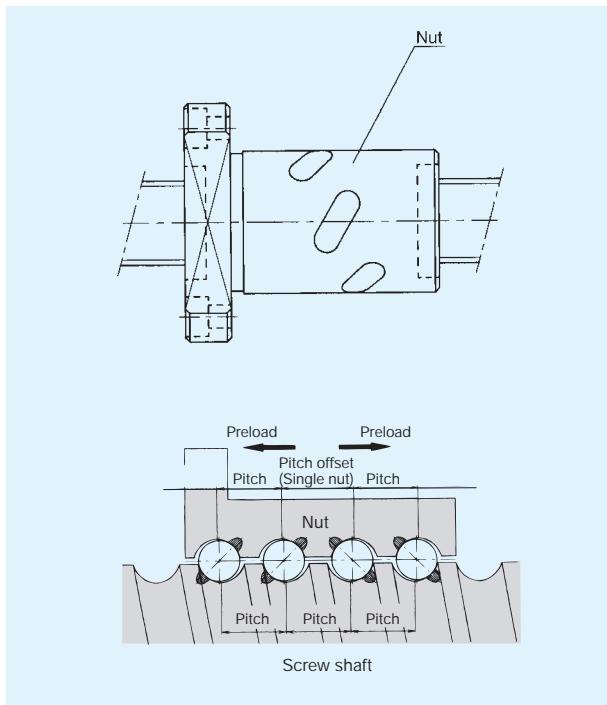

# Preload and Rigidity

## Preload

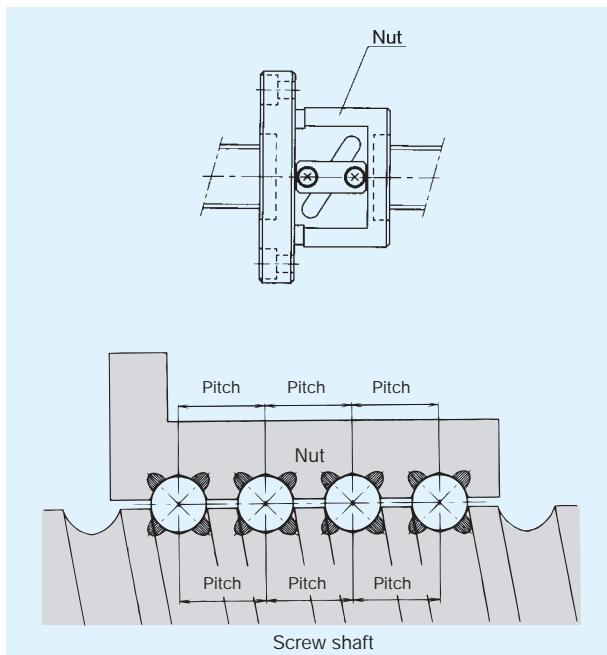

The preload eliminates the axial clearance of the ballscrew and improves the rigidity. Furthermore, the preload ensures positioning accuracy.

### Preloading methods

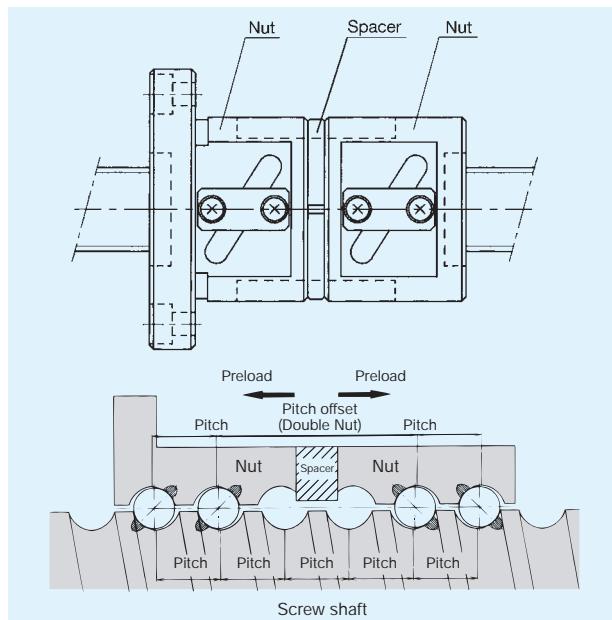

(A) Pitch shift method: The pitch is shifted at the central part of the nut to create the requested preload.

(B) Ball selection: To create the requested preload the nut is filled with balls in a certain diameter.

(C) Double nut method: Between two nuts a spacer creates the required preload.

### Rigidity of the preloaded ballscrew

Nuts A and B of a double nut ballscrew receive preload  $F_{a0}$  as a result of the spacer. The preload causes elastic displacement  $\delta_{a0}$  to be applied to both nuts. If an axial load  $F_a$  is exerted from outside under these conditions, the displacements of both nuts become as follows:

$$\delta_a = \delta_{a0} + \delta_{a1} \quad \delta_b = \delta_{a0} - \delta_{a1}$$

That is, the loads exerted on nuts A and B are as follows:

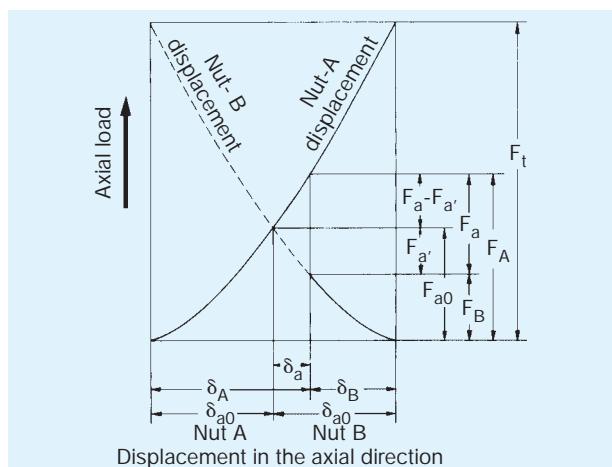

$$F_A = F_{a0} + F_a - F_{a'} = F_a + F_p \quad F_B = F_{a0} - F_{a'} = F_p$$

Axial load and elastic displacement are connected as follows:

$$\delta_{a0} = K \cdot F_{a0}^{2/3} \quad 2 \delta_{a0} = K \cdot F_1^{2/3}$$

$$\left(\frac{F_1}{F_{a0}}\right)^{2/3} = 2 \frac{\delta_{a0}}{\delta_{a0}} = 2 \quad F_t = 2.8 F_{a0} \approx 3 F_{a0}$$

The most optimum preload level is one-third of the maximum axial load. Standard values for the maximum preload are mentioned on page 2. A too high preload shortens the life time and increases the heat development.

## Axial Rigidity of the Feed-Screw System

Let the axial rigidity of a feed-screw system be  $K$ . Then, the elastic displacement in the axial direction can be obtained using equation.

$$\delta = \frac{F_a}{K}$$

$\delta$  : Feed-screw system elastic displacement in the axial direction (μm)  
 $F_a$  : applied axial load (N)

The rigidity ( $K$ ) of this feed-screw system can be obtained using equation (30).

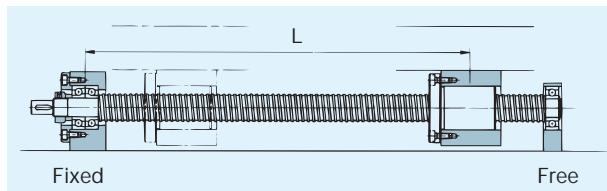

$$\frac{1}{K} = \frac{1}{K_S} + \frac{1}{K_N} + \frac{1}{K_B} + \frac{1}{K_H}$$

$K$  : axial rigidity of the feed-screw system (N/μm)  
 $K_S$  : axial rigidity of the screw shaft (N/μm)  
 $K_N$  : axial rigidity of the Nut (N/μm)  
 $K_B$  : axial rigidity of the support bearing (N/μm)  
 $K_H$  : rigidity of the Nut Bracket and support bearing bracket (N/μm)

## Axial rigidity of the screw shaft

The axial rigidity of a screw shaft varies depending on the shaft mounting method.

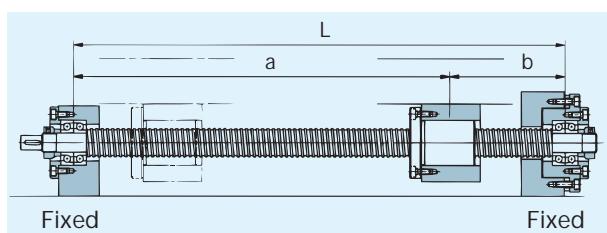

### (1) For "fixed/supported" (free)

$$K_S = \frac{A \cdot E}{1000 \cdot L}$$

$A$  : screw-shaft cross-sectional area (mm<sup>2</sup>)  
 $A = \frac{\pi}{4} d_1^2$   
 $(d_1:$  screw-shaft-thread minor diameter) (mm)  
 $E$  : Young's modulus (2.06 · 10<sup>5</sup> N/mm<sup>2</sup>)  
 $L$  : distance between mounting positions (mm)

### (2) For "fixed/fixed"

$$K_S = \frac{A \cdot E \cdot L}{1000 \cdot a \cdot b}$$

At the point at which  $a = b = \frac{L}{2}$

$K_S$  becomes the minimum and the elastic displacement in the axial direction the maximum.

$$K_S = \frac{4A \cdot E}{1000L}$$

## Axial rigidity of a nut

The axial rigidity of a Nut varies significantly depending on the preload levels.

Dimension tables include theoretical axial rigidity values when an axial load with a magnitude of 30% of the basic dynamic load rating ( $C_a$ ) is exerted on the Nut. These values, however, do not take into account the rigidity of the Nut mounting brackets. Therefore, as a general rule, take 80% of the values given in the table.

When the applied axial load with a magnitude other than 30% of the basic dynamic load rating ( $C_a$ ) is exerted on the Nut, rigidity values can be calculated using equation.

$$K_N = K \left( \frac{F_a}{0.3 C_a} \right)^{1/3} \cdot 0.8$$

where

$K_N$  : axial rigidity of the Nut (N/μm)  
 $K$  : rigidity value given in the dimension table (N/μm)  
 $F_a$  : applied axial load (N)  
 $C_a$  : basic dynamic load rating (N)

## Axial rigidity of the support bearing

The axial rigidity of the support bearings for the ballscrew varies by bearing type.

A typical calculation for determining the axial rigidity of an angular contact ball bearing can be made using equation.

$$K_B \approx \frac{3F_{a0}}{\delta_{a0}}$$

where

$K_B$  : axial rigidity of the support bearing (N/μm)  
 $F_{a0}$  : preload on the support bearing (N)  
 $\delta_{a0}$  : displacement in the axial direction (μm)

$$\delta_{a0} = \frac{0.45}{\sin \alpha} \left( \frac{Q^2}{D_a} \right)^{1/3}$$

$$Q = \frac{F_{a0}}{Z \sin \alpha}$$

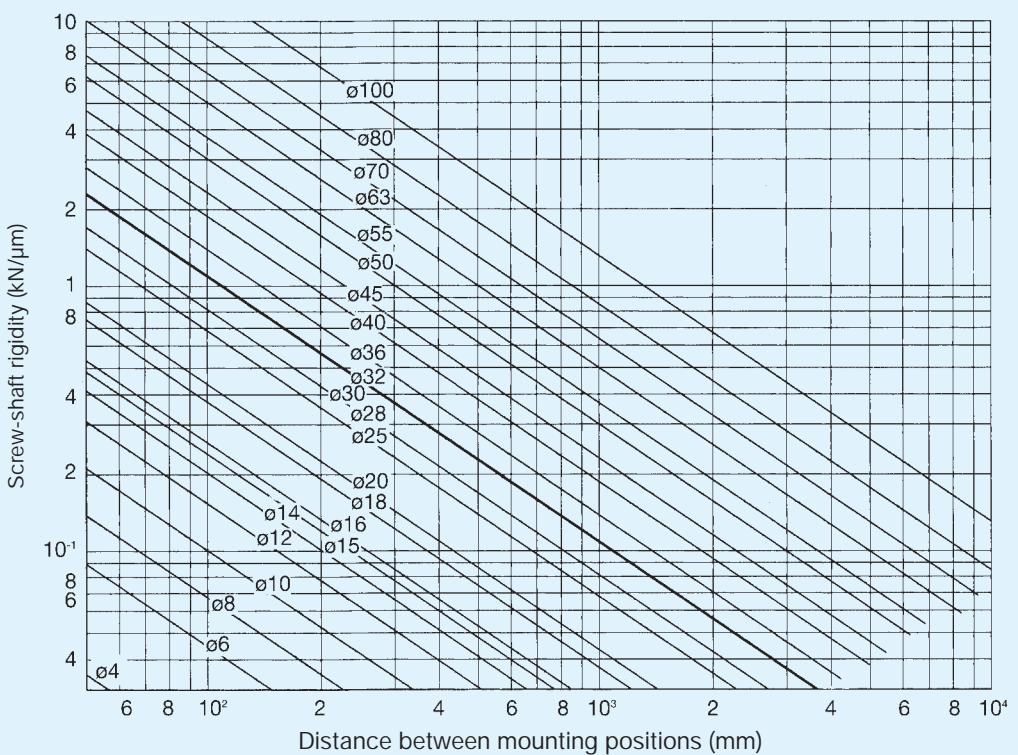

where

$Q$  : axial load (N)  
 $D_a$  : ball diameter of the support bearing (mm)  
 $\alpha$  : initial contact angle of the support bearing (°)  
 $Z$  : number of balls

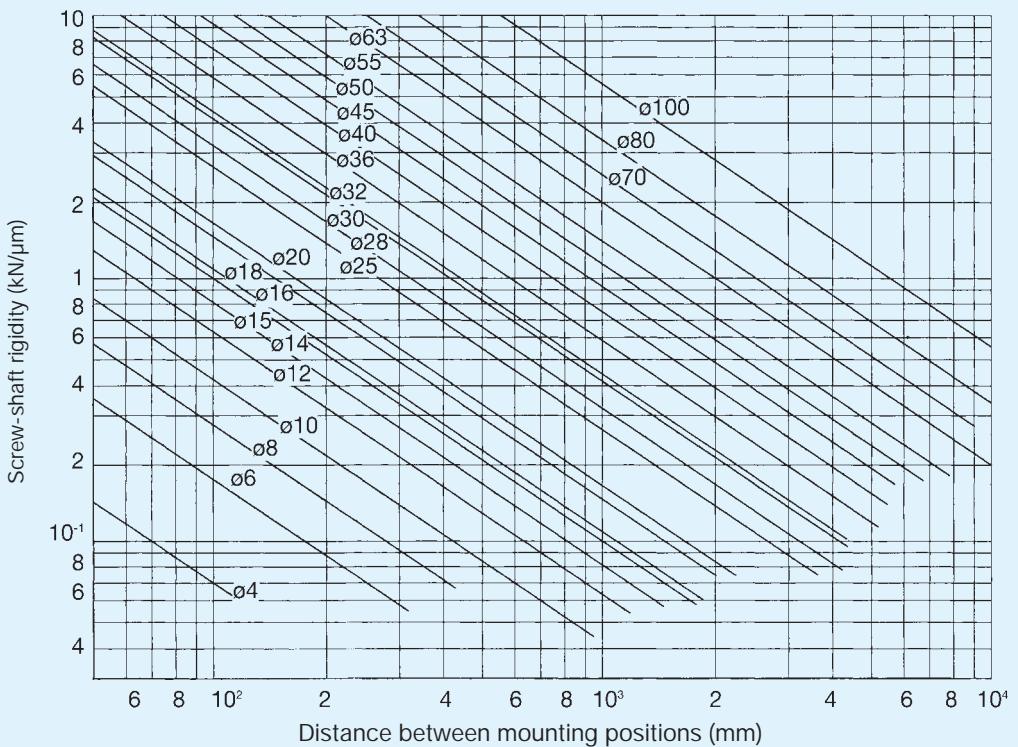

If you are not certain of these values, please contact the manufacturer of the bearing to be used.

## Axial rigidity of the nut bracket and support bearing bracket

Take this into consideration in the design of your system. Set the rigidity as high as possible.

Axial Rigidity of a Screw Shaft („Fixed/Free“ and „Fixed/Supported“)

Axial Rigidity of a Screw Shaft („Fixed/Fixed“)

# Lubrication, Handling and Installation

## Lubrication

To ensure the optimum performance of the ballscrew, the correct lubricant and lubrication method for the relevant operating conditions should be selected.

For the classification and characteristics of lubricants and lubrication methods, see page A-7.

### Amount of lubricant

Insufficient lubricant causes poor lubrication, whereas an excessive amount of lubricant generates heat and increases resistance. It is therefore important to determine the optimum amount of lubricant for the relevant operating conditions.

### Grease

The appropriate amount of grease is normally approximately 1/3 of the volume of the space within the nut.

### Oil

Table 1 gives guidelines for the amount of oil. Please note, however, that the amount of oil depends on the stroke, type of oil used, and operating conditions (e.g., need to prevent heat generation).

Table 1 Guidelines for the amount of oil  
(Interval: 3 min.)

Shaft diameter (mm)	Amount of oil (cm <sup>3</sup> )
16 ~ 18	0.07
20 ~ 25	0.10
28 ~ 32	0.15
36 ~ 40	0.25

## Handling

As friction is reduced to a very low level in the ballscrew, when it is held upright, the nut can easily fall off the screw shaft.

Please be aware of this when holding the ballscrew upright. If the nut is not in place, the balls will also fall off, which may damage the ball circulation mechanism including the return pipe. Should the nut be detached from the screw shaft, contact **THK**.

Some ballscrews have exposed ball circulation mechanisms (return pipe, end cap), so be very careful to avoid dents and similar impacts.

## Contamination Protection

Dust and foreign matter that enter the ballscrew may cause accelerated wear and breakage, as with rolling bearings. Therefore, where contamination by dust and foreign matter (e.g., cutting chips) is likely, screw shafts must always be completely covered with contamination protection devices such as bellows or screw covers. If the ballscrew is used in an atmosphere free from foreign matter but with suspended dust, the labyrinth seal (for Precision Ballscrews) and brush seal (for Rolled Ballscrews) can be used in place of contamination protection devices. When placing an order, be sure to specify the model number. The labyrinth seal is designed to maintain a clearance between the seal and screw-shaft raceway, so that torque does not develop and no heat is generated. However, its effect in contamination protection is limited.

In ballscrews other than the large-lead and super-lead types, there is no difference in nut dimensions between those with and without a seal.

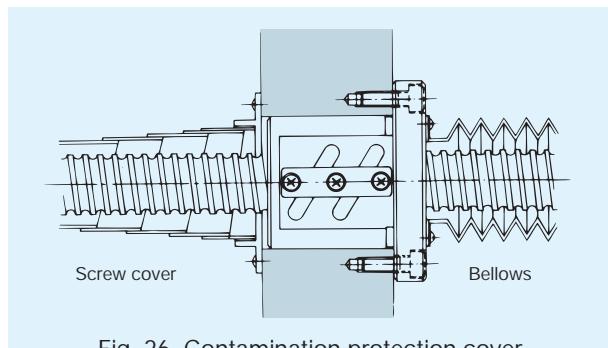

Fig. 26 Contamination protection cover

## Installation

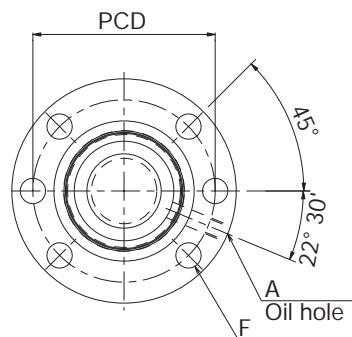

When attaching the ballscrew to a machine, do not detach the nut from the screw shaft. If it is necessary to detach the nut, apply a sleeve with a bore approximately 1 mm smaller than the screw-shaft thread minor diameter so as to prevent balls from falling off. Although the thread of the ballscrew is hardened and finished by grinding, forcible driving of a part onto the screw shaft or into the nut may cause an indentation in the raceway. When assembling parts on the screw shaft and nut, take care not to apply excessive force to the shaft and nut.

Misalignment between the screw-shaft supported portion and the nut exerts an unnatural force on the ballscrew, resulting in problems such as heavy rotation. Similar symptoms appear when the nut and the shaft supported portion are tilted. These problems accelerate wear on the ballscrew, which may significantly decrease its service life. Therefore, in terms of the mounting accuracy, pay close attention to misalignment and tilt. Upon completion of mounting, the ballscrew must be checked by moving it over the entire stroke to ensure that there is no problem with its operation.

In designing your ballscrew system, make sure that no radial load or moment is exerted on the ballscrew. Remember that a radial load or moment may significantly decrease the service life and cause malfunctions.

## Precision Ballscrew EBA

- Single nut according to DIN 69051 (1989) with flange form A
- Preload by ball selection (ground) or without preload (precision rolled)
- Ground or precision rolled screw shafts available

\* Also available with precision rolled screw shaft (Cp3 und Cp5).

<sup>1)</sup> The rigidity values in this table indicate spring constants obtained from the load and elastic displacement under a preload of 10% of the basic dynamic load rating  $C_a$ , and an axial load  $F_a$  that is three times that of the preload  $F_{a0}$ . As these values do not take into account the rigidity of the parts involved in the nut installation, take 80% of the values given in this table as a general guideline.

If the preload  $F_{a0}$  differs from 0.1  $C_a$ , the rigidity  $K_N$  can be calculated using the following equation:

$$K_N = K \cdot \left( \frac{F_{a0}}{0.1 C_a} \right)^{\frac{1}{3}} \cdot 0.8$$

If the ballscrew is not preloaded, please consult THK for the rigidity value.

\* Also available with precision rolled screw shaft (Cp3 und Cp5).

<sup>1)</sup> The rigidity values in this table indicate spring constants obtained from the load and elastic displacement under a preload of 10% of the basic dynamic load rating  $C_a$ , and an axial load  $F_a$  that is three times that of the preload  $F_{a0}$ . As these values do not take into account the rigidity of the parts involved in the nut installation, take 80% of the values given in this table as a general guideline.

If the preload  $F_{a0}$  differs from 0.1  $C_a$ , the rigidity  $K_N$  can be calculated using the following equation:

$$K_N = K \cdot \left( \frac{F_{a0}}{0.1 C_a} \right)^{\frac{1}{3}} \cdot 0.8$$

If the ballscrew is not preloaded, please consult **THK** for the rigidity value.

\* Also available with precision rolled screw shaft (Cp3 und Cp5).

<sup>1)</sup> The rigidity values in this table indicate spring constants obtained from the load and elastic displacement under a preload of 10% of the basic dynamic load rating  $C_a$ , and an axial load  $F_a$  that is three times that of the preload  $F_{a0}$ . As these values do not take into account the rigidity of the parts involved in the nut installation, take 80% of the values given in this table as a general guideline.

If the preload  $F_{a0}$  differs from 0.1  $C_a$ , the rigidity  $K_N$  can be calculated using the following equation:

$$K_N = K \cdot \left( \frac{F_{a0}}{0.1 C_a} \right)^{\frac{1}{3}} \cdot 0.8$$

If the ballscrew is not preloaded, please consult THK for the rigidity value.
